1. Peptide prep
2. Generate 3 conformations from sequence(helix,sheet,ppii)
3. Generate peptide ensemble of the 3 conformations
4. Using pymol

1.defining active restraint(one for protein and one for peptide)

2.protien's active restraint(specific list of numbers) in peptide(whole sequence)

3. how to check the numbering of amino acids(MD analysis)

We should give option for uploading the users own custom config file, use default if none provided(custom docking in celiacdb)

Finally run haddock3 on the peptide, and show results

In haddock give option for choosing active residues for defining the restraints or let it stay default

While uploading peptide, give option for defining active residues for peptide for restraints

Check if we can generate conformers on local host

Update data on celiacdb
